

X-ray nonlinear optics with XFEL

Kenji Tamasaku (RIKEN)

1. X-ray PDC
2. Nonlinear spectroscopy

X-ray parametric down-conversion into SX, EUV, VUV, UV, visible, infrared regions

Parametric Down-conversion
(2nd order nonlinear process)

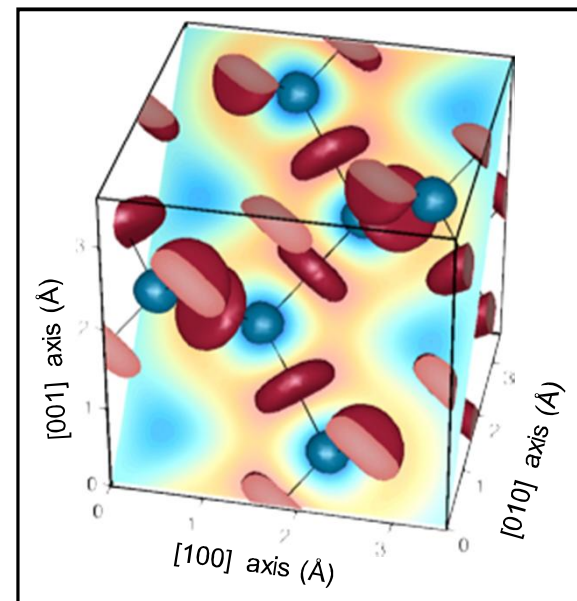

PDC can reveal optical response at longer wavelength with the atomic resolution.

(Sum-frequency generation with synchronized Ti:Sa laser also gives the same information for UV, V and IR.)

Example)

Structure of linear susceptibility, $\chi(r)$, at 207 Å with 0.54-Å ($=\lambda/380$) resolution.

Sample: diamond
 E_1 (pump): 11.107 keV
 E_3 (idler): 60 eV

K.Tamasaku et al., Nat. Phys. 7, 705 (2011)

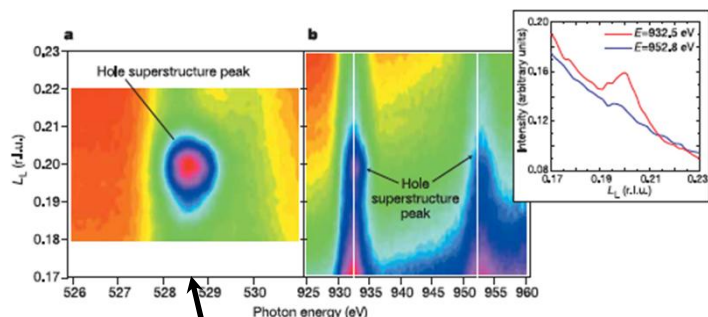

$X \rightarrow X+SX$ PDC for materials science

Ex) Investigation of charge order

- X-ray and neutron diffraction sees mainly lattice distortion (not charge order).
- SX diffraction is powerful tool.

But,

Abbamonte, *Nature* **431**, 1078 (2004).

Oxygen *K*-edge

23 Å : *not enough resolution*

Sample environment is not flexible due to absorption.

Soft x-ray diffraction

X-ray PDC
can realize Å resolution
at O 1s \rightarrow 2p resonance

We need spectral brightness of XFEL!

Is nonlinear spectroscopy possible with XFEL?

SACLA

1- μ J & 5-fs pulse w 1- μ m² focusing

Two-photon absorption is measurable.

XFEL:

10⁹ ph/pulse, 5 keV ~ 1 μ J

500-fs pulse w 100-nm² focusing

may allow observation of TPA.

We can consider nonlinear spectroscopy with XFEL

- ❖ X-ray two-photon absorption spectroscopy
to access the 1s-3d transition.
- ❖ Stimulated Raman scattering(?)
to measure XAS of lighter materials.
Need for two-color X-rays (XFEL+Spontaneous X-rays).
